Problem 4: Proofs and Derivation	
a. Prove $\nabla_x(x^Ta) = \nabla_x(a^Tx) = a$	
b. Prove $\nabla_x(x^TAx) = (A+A^T)x$	
c. Prove $\nabla_x(x^TAx) = 2Ax$	
d. Prove $\nabla_x ((Ax+b)^T * (Ax+b)) = 2A^T (Ax+b)$	

Problem 1: Python and NumPy Warm-up Exercises

Please refer to *homework1_template.py* for solutions of 1(a) to 1(n).

Problem 2: Linear Regression via Analytical Solution

a. Age Regressor:

- We have implemented linear regression via analytical solution using linear algebraic operations in NumPy. Find the methods *linear_regression* and *train_age_regressor* in *homework1_template.py*.
 - o Note: Before running the script, please include the datasets in the same folder.
- Analytical Solution to obtain the weights (w):

FMSE (4191W) = 1 = (a(x (0) W) - 4 (1))
$f_{MSE}(y_i g_j w) = \frac{1}{2n} \left(g(x^{(i)}; w) - y^{(i)} \right)^2$
$= \frac{1}{2n} \left(\chi^{(i)} W - y^{(i)} \right)^{2}$ $= \frac{1}{2n} \left[\chi^{(i)} W - y^{(i)} \right]^{2}$
-> Solving for W
$\nabla w f_{MSE}(y_j \hat{y}_j w) = \nabla w \left[\frac{1}{2m} \sum_{i=1}^{m} (\chi^{(i)} w - y^{(i)})^2 \right]$
$= \frac{1}{2n} \sum_{i=1}^{N} \sqrt{\left(\chi^{(i)}W - y^{(i)}\right)^{2}}$
$=\frac{1}{n}\sum_{i=1}^{n}\chi^{(i)}\left(\chi^{(i)}W-y^{(i)}\right)$
n i=1
By setting to 0, splitting the Sum apart, a solving, we reach the solution:
Jw fase (y, y, w) = 1 = 200 (20) W - y (0)
$0 = \sum_{i} \chi^{(i)} \chi^{(i)} \frac{7}{W - \sum_{i} \chi^{(i)} \chi^{(i)}}$
t v c

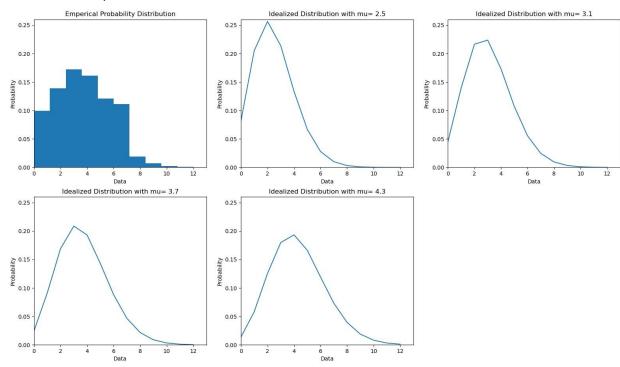

$$\begin{aligned}

& \underbrace{\mathbb{E}_{X}^{(i)} \times \mathbb{V}^{T}}_{i} &= \underbrace{\mathbb{E}_{X}^{(i)} \times \mathbb{V}^{T}}_{i} \\
& \underbrace{\mathbb{E}_{X}^{(i)} \times \mathbb{V}^{T}}_{i} &= \underbrace{\mathbb{E}_{X}^{(i)} \times \mathbb{V}^{T}}_{i} \\
& \underbrace{\mathbb{E}_{X}^{(i)} \times \mathbb{V}^{T}}_{i} &= \underbrace{\mathbb{E}_{X}$$

 After optimizing the weights on training set, we then computed the cost f_{MSE} on both testing and training dataset. The output is reported below:

> Training Loss: 50.46582283534778 Testing Loss: 268.7869643405511

Problem 3: Probability Distributions

- a. Estimating the Parameters of a Probability Distribution:
 - We have plotted the empirical probability of the data in *PoissonX.npy*.
 - Next, we plotted the probability distribution of a Poisson random variable with the following rate parameters: 2.5, 3.1, 3.7, and 4.3.
 - The plots are as shown below:

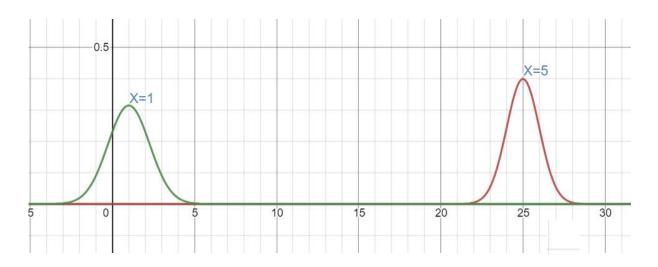

Based on observations the parameter value of mu=3.7 is most consistent with the data.

b. Conditional Probability Distributions to Represent the Uncertainty of Functions:

i. The corresponding value of y tend to be larger for the values of x with large magnitude as mean of the given normal distribution varies according to x^2 . We can observe in the graph below that at x=5 the mean of distribution is 25 therefore indicating that y would be large.

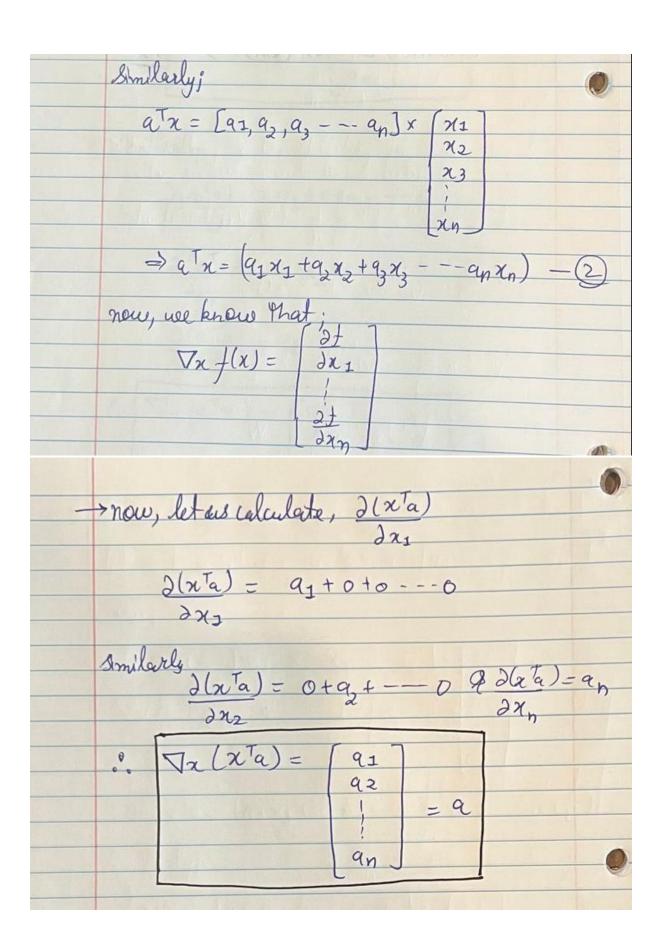

ii. The uncertainty in the corresponding value of y tend to be larger for the values of x with small magnitude. We can observe in the graph below that at x=1 the spread is more when compared to x=5. More spread indicates that the uncertainty is higher for lower value of x.

<u>Problem 4:</u> Proofs and Derivation

a. Prove $\nabla_x(x^Ta) = \nabla_x(a^Tx) = a$
